"JnanaSangama", Belgaum -590014, Karnataka.

LAB REPORT

on

Machine Learning

Submitted by:

Abhinav Ishan

(1BM21CS273)

Under the Guidance of
Dr Seema Patil
Assistant Professor, BMSCE

in partial fulfillment for the award of the degree of

BACHELOR OF ENGINEERING

in

COMPUTER SCIENCE AND ENGINEERING

B.M.S. COLLEGE OF ENGINEERING
(Autonomous Institution under VTU)
BENGALURU-560019

B. M. S. College of Engineering,

Bull Temple Road, Bangalore 560019

(Affiliated To Visvesvaraya Technological University, Belgaum)

Department of Computer Science and Engineering

CERTIFICATE

This is to certify that the Lab work entitled "**Machine Learning**" carried out by **Abhinav Ishan (1BM21CS273),** who is a bonafide student of **B. M. S. College of Engineering.** It is in partial fulfillment for the award of **Bachelor of Engineering in Computer Science and Engineering** of the Visvesvaraya Technological University, Belgaum during the year 2024. The Lab report has been approved as it satisfies the academic requirements in respect of **Machine Learning - (22CS6PCMAL)** work prescribed for the said degree.

Dr Seema Patil
Associate Professor
Department of CSE
BMSCE, Bengaluru

Dr. Jyothi S Nayak
Professor and Head
Department of CSE
BMSCE, Bengaluru

Table Of Contents

1. Course Outcomes

CO1: Apply machine learning techniques in computing systems.

CO2: Evaluate the model using metrics.

CO3: Design a model using machine learning to solve a problem.

CO4: Conduct experiments to solve real-world problems using appropriate machine learning techniques

2. Experiments

2.1 Experiment - 1

2.1.1 Question:

Write a python program to import and export data using Pandas library functions.

2.1.2 Code with Output:

```
import pandas as pd
import numpy as np

california_housing_train_data = pd.read_csv("/content/sample_data/california_housing_train.csv")

# View the first 5 rows

california_housing_train_data.head()
```

	longitude	latitude	housing_median_age	total_rooms	total_bedrooms	population	households	median_income	median_house_value
0	-114.31	34.19	15.0	5612.0	1283.0	1015.0	472.0	1.4936	66900.0
1	-114.47	34.40	19.0	7650.0	1901.0	1129.0	463.0	1.8200	80100.0
2	-114.56	33.69	17.0	720.0	174.0	333.0	117.0	1.6509	85700.0
3	-114.57	33.64	14.0	1501.0	337.0	515.0	226.0	3.1917	73400.0
4	-114.57	33.57	20.0	1454.0	326.0	624.0	262.0	1.9250	65500.0

```
import pandas as pd
import numpy as np

url = "https://archive.ics.uci.edu/ml/machine-learning-databases/iris/iris.data"

# Define the column names

col_names = ["sepal_length_in_cm",
"sepal_width_in_cm",
"petal_length_in_cm",
"petal_width_in_cm",
"class"]

# Read data from URL

iris_data = pd.read_csv(url, names=col_names)
iris_data.head()
```

	sepal_length_in_cm	sepal_width_in_cm	petal_length_in_cm	petal_width_in_cm	class
0	5.1	3.5	1.4	0.2	Iris-setosa
1	4.9	3.0	1.4	0.2	Iris-setosa
2	4.7	3.2	1.3	0.2	Iris-setosa
3	4.6	3.1	1.5	0.2	Iris-setosa
4	5.0	3.6	1.4	0.2	Iris-setosa

```
[3] iris_data.to_csv("cleaned_iris_data.csv")
```

2.2 Experiment - 2

2.2.1 Question:

End-to-end ML Project.

2.2.2 Code with Output:

Download the Data

In [1]:
```
import os
import tarfile
import urllib
```

In [2]:
```
DOWNLOAD_ROOT = "https://raw.githubusercontent.com/ageron/handson-ml2/master/"
HOUSING_PATH = os.path.join("data", "01")
HOUSING_URL = DOWNLOAD_ROOT + "datasets/housing/housing.tgz"
```

In [3]:
```
def fetch_housing_data(housing_url=HOUSING_URL, housing_path=HOUSING_PATH):
    os.makedirs(name=housing_path, exist_ok=True)
    tgz_path = os.path.join(housing_path, "housing.tgz")
    urllib.request.urlretrieve(url=housing_url, filename=tgz_path)
    housing_tgz = tarfile.open(name=tgz_path)
    housing_tgz.extractall(path=housing_path)
    housing_tgz.close()
```

Download the data:

In [4]:
```
fetch_housing_data()
```

Load the data using pandas:

In [5]:
```
import pandas as pd
```

In [6]:
```
def load_housing_data(housing_path=HOUSING_PATH):
    data_path = os.path.join(housing_path, "housing.csv")
    return pd.read_csv(data_path)
```

Data Structure

In [7]:
```
housing = load_housing_data()
```

In [8]:
```
housing.head()
```

Out[8]:

	longitude	latitude	housing_median_age	total_rooms	total_bedrooms	population	households	median_income	median_house_value
0	-122.23	37.88	41.0	880.0	129.0	322.0	126.0	8.3252	452600.0
1	-122.22	37.86	21.0	7099.0	1106.0	2401.0	1138.0	8.3014	358500.0
2	-122.24	37.85	52.0	1467.0	190.0	496.0	177.0	7.2574	352100.0
3	-122.25	37.85	52.0	1274.0	235.0	558.0	219.0	5.6431	341300.0
4	-122.25	37.85	52.0	1627.0	280.0	565.0	259.0	3.8462	342200.0

```
In [9]: housing.info()
```

```
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 20640 entries, 0 to 20639
Data columns (total 10 columns):
 #   Column              Non-Null Count  Dtype
---  ------              --------------  -----
 0   longitude           20640 non-null  float64
 1   latitude            20640 non-null  float64
 2   housing_median_age  20640 non-null  float64
 3   total_rooms         20640 non-null  float64
 4   total_bedrooms      20433 non-null  float64
 5   population          20640 non-null  float64
 6   households          20640 non-null  float64
 7   median_income       20640 non-null  float64
 8   median_house_value  20640 non-null  float64
 9   ocean_proximity     20640 non-null  object
dtypes: float64(9), object(1)
memory usage: 1.6+ MB
```

There exist $20,640$ instances (rows) in the dataset. Which means that it is fairly small data sample by machine learning standards.

207 districts are missing the `total_bedrooms` attribute, we will need to take care of this later.

On the other hand, all attributes are numerical, except `ocean_proximity`

Since we noticed repeated `ocean_proximity` values for the top 5 rows, we suspect that it is a categorical column, let's check it out:

```
In [10]: housing['ocean_proximity'].value_counts()
```

```
Out[10]: ocean_proximity
<1H OCEAN     9136
INLAND        6551
NEAR OCEAN    2658
NEAR BAY      2290
ISLAND           5
Name: count, dtype: int64
```

```
In [11]: housing.describe()
```

Out[11]:

	longitude	latitude	housing_median_age	total_rooms	total_bedrooms	population	households	median_income	me

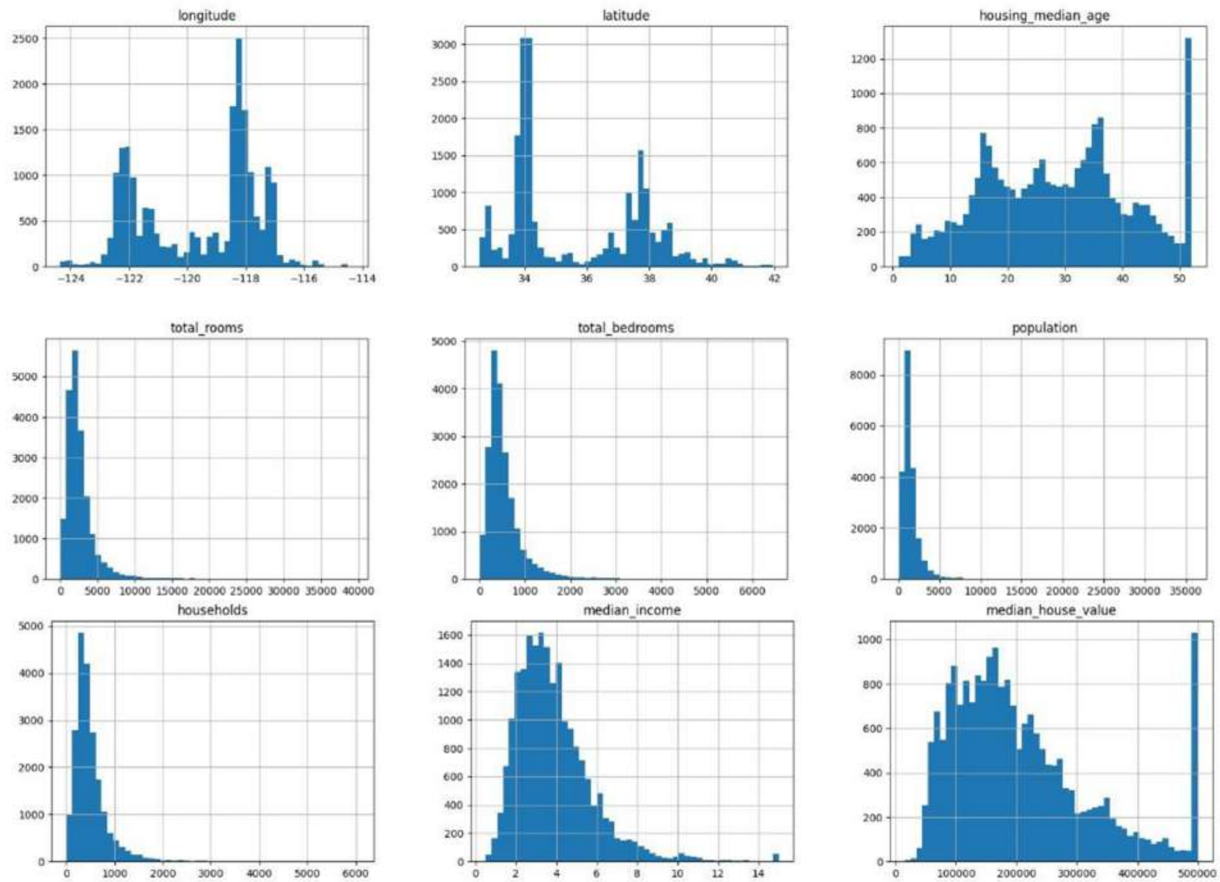
In [12]:

```python
import matplotlib.pyplot as plt
import seaborn as sns
```

In [13]:

```python
housing.hist(bins=50, figsize=(20,15))
plt.show()
```



Create a Test Set

In [14]:

```python
import numpy as np
```

In [15]:

```python
def split_train_test(data, test_ratio=0.2):
    shuffled_indices = np.random.permutation(len(data))
    test_set_size = int(len(data) * test_ratio)
    test_indices = shuffled_indices[:test_set_size]
    train_indices = shuffled_indices[test_set_size:]
    return data.iloc[train_indices], data.iloc[test_indices]
```

In [16]:

```python
# you can then use the function like this
train_set, test_set = split_train_test(data=housing)
len(train_set), len(test_set)
```

Out[16]: (16512, 4128)

In [17]:
```
from zlib import crc32
```

In [18]:
```
def test_set_check(identifier, test_ratio=.2):
    total_size = 2**32
    hex_repr = crc32(np.int64(identifier)) & 0xffffffff
    in_test = hex_repr < (test_ratio * total_size)
    return in_test
```

In [19]:
```
[test_set_check(i) for i in range(10)]
```

Out[19]:
```
[False, False, True, False, False, True, False, False, False, False]
```

In [20]:
```
def split_train_test_by_id(data, test_ratio, id_column):
    ids = data[id_column]
    in_test_set = ids.apply(lambda id_: test_set_check(id_, test_ratio))
    return data.loc[~in_test_set], data.loc[in_test_set]
```

Unfortunately, the housing dataset does not have an identifier, column. We will use the row index as an identifier:

In [21]:
```
housing_with_id = housing.reset_index()
```

In [22]:
```
train_set, test_set = split_train_test_by_id(data=housing_with_id, test_ratio=0.2, id_column="index")
train_set.shape, test_set.shape
```

Out[22]:
```
((16512, 11), (4128, 11))
```

In [23]:
```
def from_Z_to_N(z):
    if z >= 0:
        n = 2 * z
    else:
        n = -2 * z - 1
    return n
```

In [24]:
```
def cantor_pairing(n1, n2):
    n = ( ( (n1 + n2) * (n1 + n2 + 1) ) / 2 ) + n2
    return n
```

In [25]:
```
def lat_lon_to_index(lat, lon):
    lat, lon = int(lat*100), int(lon*100)
    lat, lon = from_Z_to_N(lat), from_Z_to_N(lon)
    index = cantor_pairing(lat, lon)
    return np.int64(index)
```

In [26]:
```
housing['id'] = housing.apply(lambda row: lat_lon_to_index(row['latitude'], row['longitude']), axis=1)
```

In [27]:
```
housing['id'].value_counts()
```

Out[27]:
```
id
513289261    24
513481522    20
513417431    18
513353344    18
463609694    14
             ..
513032709     1
513417159     1
519523778     1
519459311     1
515855387     1
Name: count, Length: 11573, dtype: int64
```

We still get duplicate indexes, and at the same time, we have duplicate (lat,lon) tuples as follows:

In [28]:
```
housing.groupby(by=['longitude', 'latitude']).count()['total_rooms'].sort_values()
```

Out[28]:
```
longitude  latitude
-124.35    40.54        1
-118.90    34.41        1
           35.26        1
           35.41        1
-118.89    34.22        1
                       ..
-122.41    37.75       10
-122.42    37.75       10
-122.44    37.78       11
-122.42    37.80       11
-122.41    37.80       15
Name: total_rooms, Length: 12590, dtype: int64
```

In [29]:
```
del(housing['id'])
```

In [30]:
```
housing_with_id["id"] = housing["longitude"] * 1000 + housing["latitude"]
```

In [31]:
```
train_set, test_set = split_train_test_by_id(data=housing_with_id, test_ratio=0.2, id_column='id')
train_set.shape, test_set.shape
```

Out[31]: ((16322, 12), (4318, 12))

Split the dataset

In [32]:
```
from sklearn.model_selection import train_test_split
```

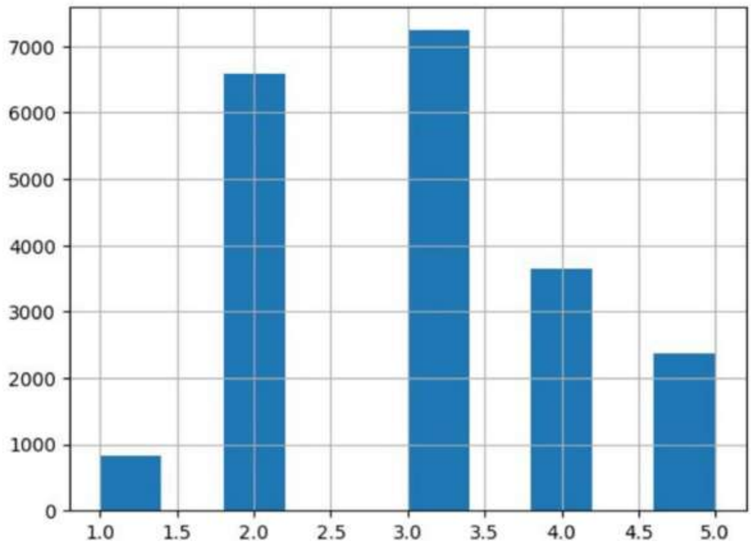
In [33]:
```
train_set, test_set = train_test_split(housing, test_size=0.2, random_state=42)
train_set.shape, test_set.shape
```

Out[33]: ((16512, 10), (4128, 10))

In [34]:
```
housing['income_cat'] = pd.cut(x=housing['median_income'], bins=[0, 1.5, 3, 4.5, 6, np.inf], labels=[1, 2, 3, 4, 5])
```

In [35]:
```python
# visualize the categories
housing['income_cat'].hist()
```

Out[35]: <Axes: >



Now we are ready to do stratified sampling based on income category:

In [36]:
```python
from sklearn.model_selection import StratifiedShuffleSplit
```

In [37]:
```python
split = StratifiedShuffleSplit(n_splits=1, test_size=0.2, random_state=42)
```

In [38]:
```python
for train_index, test_index in split.split(X=housing, y=housing['income_cat']):
    strat_train_set = housing.loc[train_index]
    strat_test_set = housing.loc[test_index]
```

checking the proportions of income categories in the test set:

In [39]:
```python
strat_test_set['income_cat'].value_counts() / len(strat_test_set)
```

Out[39]:
```
income_cat
3    0.350533
2    0.318798
4    0.176357
5    0.114341
1    0.039971
Name: count, dtype: float64
```

Now that we have a test set that is representative of `income_cat` 's distribution, it's time to remove it:

In [40]:
```python
for set_ in (strat_train_set, strat_test_set):
    set_.drop('income_cat', axis=1, inplace=True)
```

3.Discover & Visualize the Data to Gain Insights

Exploring the training set:

In [41]:
```
strat_train_set.shape, strat_test_set.shape
```

Out[41]:
```
((16512, 10), (4128, 10))
```

In [43]:
```
strat_test_set.reset_index().to_feather(fname='data/01/strat_test_set.f')
```

```
---------------------------------------------------------------------------
TypeError                                 Traceback (most recent call last)
<ipython-input-43-044385fea95e> in <cell line: 1>()
----> 1 strat_test_set.reset_index().to_feather(fname='data/01/strat_test_set.f')

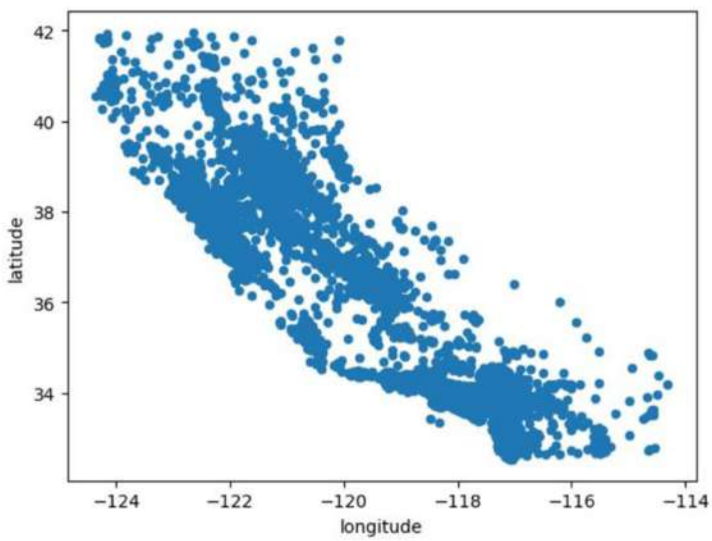
TypeError: DataFrame.to_feather() missing 1 required positional argument: 'path'
```

Let's create a copy of the training set to test without harming the original one:

In [44]:
```
housing = strat_train_set.copy(); housing.shape
```

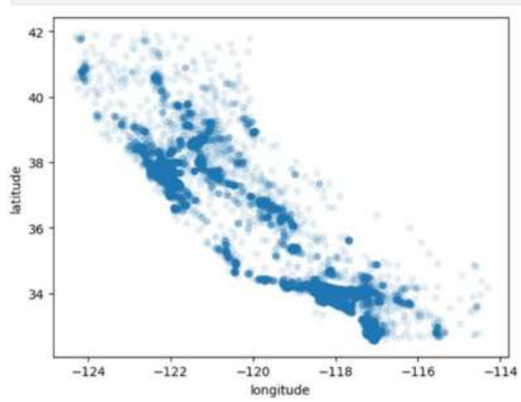
Out[44]:
```
(16512, 10)
```

In [45]:
```
housing.plot(kind='scatter', x='longitude', y='latitude')
plt.show()
```



This looks like california, but other than that, we can't really see any other pattern. Setting the alpha to 0.1 makes it much easier to estimate densities:

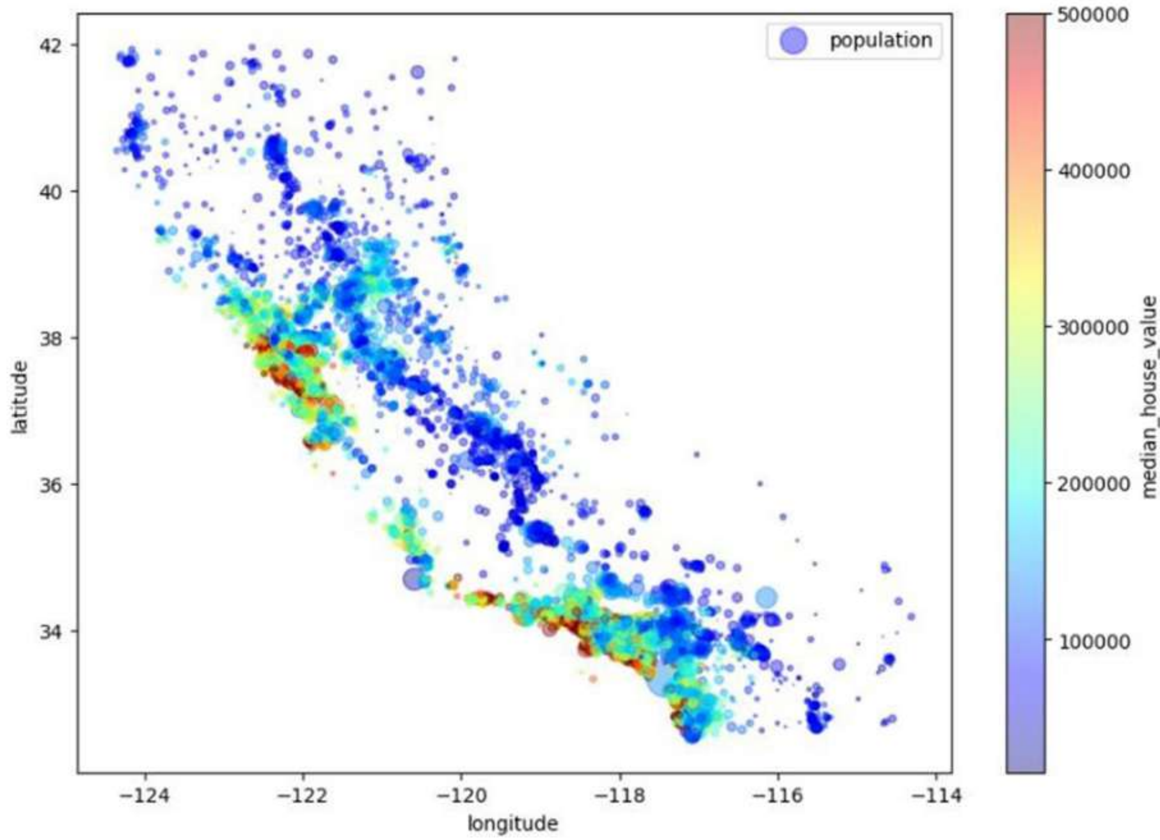
In [46]:
```
housing.plot(kind='scatter', x='longitude', y='latitude', alpha=0.1)
plt.show()
```



In the following figure, the radius of each circle represents the district's population (option `s`). The color represents the price (option `c`). We will also use a pre-defined color map called **jet** (option `cmap`) which ranges from `blue` (low levels) to `red` (high level).

In [47]:
```
housing.plot(kind='scatter', x='longitude', y='latitude', alpha=.4, s=housing['population']/100.,
             label='population', figsize=(10, 7), c='median_house_value', cmap=plt.get_cmap(name='jet'), colorbar=True)
plt.legend()
```

Out[47]: `<matplotlib.legend.Legend at 0x7a8306385630>`



Experimenting with Attribute Combinations

We may want to transform tail heavy distributions using the logarithm function ($log(.)$).

In [56]:
```
housing['rooms_per_household'] = housing['total_rooms']/housing['households']
housing['bedrooms_per_room'] = housing['total_bedrooms']/housing['total_rooms']
housing['population_per_household'] = housing['population']/housing['households']
```

Look at the correlation matrix again:

In [57]:
```
corr_matrix = housing.corr()
corr_matrix['median_house_value'].sort_values(ascending=False)
```

We notice that `bedrooms_per_room` is much more correlated with `median_house_value`. meaning that the more expensive the house, the less the `bedrooms per room` ratio. `rooms_per_household` have a moderate positive correlation with `median_house_value`, the more expensive a house is, the more rooms it will have.

4. Prepare the Data for Machine Learning Algorithms

In [58]:

```
housing = strat_train_set.drop("median_house_value", axis=1)
housing_labels = strat_train_set["median_house_value"].copy()
housing.shape, housing_labels.shape
```

Out[58]: ((16512, 9), (16512,))

Data Cleaning

We saw earlier that `total_bedrooms` have missing values, we have 3 options:

1. Get rid of the corresponding districts
   - `housing.dropna(subset='total_bedrooms')`
2. Get rid of the whole attribute (feature)
   - `housing.drop('total_bedrooms', axis=1)`
3. Set the missing values to some value (zero, mean, median, regressor preds,...)
   - `median = housing['total_bedrooms'].median()`
   - `housing['total_bedrooms'].fillna(median, inplace=True)`

We can also use `scikit-learn`'s `SimpleImputer`:

In [59]:

```
from sklearn.impute import SimpleImputer
```

In [60]:

```
imputer = SimpleImputer(strategy='median')
```

Since the imputer can only work on numerical attributes, we need to create a copy of the dataFrame without the `OCEAN_PROXIMITY` text attribute:

In [61]:

```
housing_num = housing.drop("ocean_proximity", axis=1)
```

In [61]:

```
housing_num = housing.drop("ocean_proximity", axis=1)
```

Now we can just fit the imputer to the dataframe:

In [62]:

```
imputer.fit(housing_num)
```

Out[62]: SimpleImputer(strategy='median')

In a Jupyter environment, please rerun this cell to show the HTML representation or trust the notebook.
On GitHub, the HTML representation is unable to render, please try loading this page with nbviewer.org.

The imputer has calculated the median of all attributes and stored them in `.statistics_`.

In [63]:

```
imputer.statistics_
```

Out[63]:

```
array([-118.51    ,   34.26    ,   29.     , 2119.     ,  433.     ,
       1164.     ,  408.     ,    3.54155])
```

In [64]:

```
housing_num.median().values
```

Out[64]:

```
array([-118.51    ,   34.26    ,   29.     , 2119.     ,  433.     ,
       1164.     ,  408.     ,    3.54155])
```

Now we can use the "trained or fitted" imputer to transform the numerical attributes by replacing missing values with their corresponding medians:

In [65]:

```
X = imputer.transform(housing_num)
X.shape
```

Out[65]: (16512, 8)

The result is a numpy array containing the transformed features. If we want to put it back into a Pandas DataFrame, it's simple:

In [66]:

```
housing_tr = pd.DataFrame(data=X, index=housing_num.index, columns=housing_num.columns)
housing_tr.head()
```

Out[66]:

	longitude	latitude	housing_median_age	total_rooms	total_bedrooms	population	households	median_income
12655	-121.46	38.52	29.0	3873.0	797.0	2237.0	706.0	2.1736

Handling Text & Categorical Attributes

In [67]:

```
housing_cat = housing[['ocean_proximity']]
housing_cat.head(10)
```

Out[67]:

	ocean_proximity
12655	INLAND
15502	NEAR OCEAN
2908	INLAND
14053	NEAR OCEAN
20496	<1H OCEAN
1481	NEAR BAY
18125	<1H OCEAN
5830	<1H OCEAN
17989	<1H OCEAN
4861	<1H OCEAN

In [68]:
```
housing_cat['ocean_proximity'].value_counts()
```

Out[68]:
```
ocean_proximity
<1H OCEAN     7277
INLAND        5262
NEAR OCEAN    2124
NEAR BAY      1847
ISLAND           2
Name: count, dtype: int64
```

Most ML algorithms prefer to work with numbers, so let's convert the text into **ordinal categorical** numbers:

In [69]:
```
from sklearn.preprocessing import OrdinalEncoder
```

In [70]:
```
ordinal_encoder = OrdinalEncoder()
```

In [71]:
```
housing_cat_encoded = ordinal_encoder.fit_transform(housing_cat.values)
housing_cat_encoded.shape
```

Out[71]:
```
(16512, 1)
```

In [72]:
```
housing_cat_encoded[:10]
```

Out[72]:
```
array([[1.],
       [4.],
       [1.],
       [4.],
       [0.],
       [3.],
       [0.],
       [0.],
       [0.],
       [0.]])
```

We can get the list of categories using the `categories_` attribute of the `OrdinalEncoder`:

In [73]:
```
ordinal_encoder.categories_
```

Out[73]:
```
[array(['<1H OCEAN', 'INLAND', 'ISLAND', 'NEAR BAY', 'NEAR OCEAN'],
       dtype=object)]
```

One issue with this representation is that the encoder will assume that two nearby categories are more similar than distant ones, but this is not the case for us (ex. categories 0 and 4 are clearly more similar than 0 and 1). To fix this issue, we create one binary attribute per category:

- One attribute is equal to `1` if the category is equal to `<1H OCEAN` and `0` otherwise.
- One attribute is equal to `1` if the category is equal to `INLAND` and `0` otherwise.
- ...

This is called 1-hot encoding because, for any row, only one binary attribute will be equal to 1 (hot), while the others are 0s (cold).

The new attributes are sometimes called dummy attributes, let's create them:

In [75]:

```
from sklearn.preprocessing import OneHotEncoder
```

In [76]:

```
one_hot_encoder = OneHotEncoder()
```

In [77]:

```
housing_cat_1hot = one_hot_encoder.fit_transform(housing_cat.values)
housing_cat_1hot
```

Out[77]:

```
<16512x5 sparse matrix of type '<class 'numpy.float64'>'
	with 16512 stored elements in Compressed Sparse Row format>
```

The output is a sparse scipy matrix instead of a numpy array. If we use numpy, we have to store all of the zeros in memory, comprising of most of the array. Instead, we store the information as a Scipy sparse matrix which only stores the locations of the non-zeros (which is more efficient).

We can mostly use it as a normal `2D` array, but if we want to convert it into a dense numpy array:

In [78]:

```
housing_cat_1hot.toarray()
```

Out[78]:

```
array([[0., 1., 0., 0., 0.],
       [0., 0., 0., 0., 1.],
       [0., 1., 0., 0., 0.],
       ...,
       [1., 0., 0., 0., 0.],
       [1., 0., 0., 0., 0.],
       [0., 1., 0., 0., 0.]])
```

In [79]:

```
one_hot_encoder.categories_
```

Out[79]:

```
[array(['<1H OCEAN', 'INLAND', 'ISLAND', 'NEAR BAY', 'NEAR OCEAN'],
       dtype=object)]
```

Custom Transformers

Although `scikit-learn` provide many useful transformers, we will need to write our own for custom tasks such as data cleanup or feature engineering. We'll want our transformer to easily work with other scikit-learn functionalities (such as Pipelines).

All we need to do is create a class with 3 methods: `fit`, `transform`, `fit_transform`. We can get `fit_transform` for free by adding `TransformerMixin` as a base class.

If we add `BaseEstimator` as another base class & avoid the use of *args* and *kwargs*, we get two extra methods (`.get_params()` & `.set_params()`).

In [80]:

```
from sklearn.base import TransformerMixin, BaseEstimator
```

In [81]:

```
rooms_ix, bedrooms_ix, population_ix, households_ix = 3, 4, 5, 6
```

In [82]:
```
class CombinedAttributesAdder(BaseEstimator, TransformerMixin):
    def __init__(self, add_bedrooms_per_room=True):
        self.add_bedrooms_per_room = add_bedrooms_per_room

    def fit(self, X, y=None):
        return self  # We don't have any internal parameters. Only interested in transforming data.

    def transform(self, X, y=None):
        rooms_per_household = X[:, rooms_ix] / X[:, households_ix]
        population_per_household = X[:, population_ix] / X[:, households_ix]
        if self.add_bedrooms_per_room:
            bedrooms_per_room = X[:, bedrooms_ix] / X[:, rooms_ix]
            return np.c_[X, rooms_per_household, population_per_household, bedrooms_per_room]
        else:
            return np.c_[X, rooms_per_household, population_per_household]
```

In [83]:
```
attr_adder = CombinedAttributesAdder(add_bedrooms_per_room=False)
```

In [84]:
```
housing_extra_attribs = attr_adder.transform(housing.values)
```

The `add_bedrooms_per_room` hyper-parameter will easily help us find out whether adding the attributes helps the ML algorithm or not.

We can add hyper-parameters to control any pre-processing step that we're not sure about. The more we automate these data preprocessing steps, the more combinations we get to try out.

Transformation Pipelines

In [85]:
```
from sklearn.pipeline import Pipeline
from sklearn.preprocessing import StandardScaler
```

In [86]:
```
num_pipeline = Pipeline([
    ('imputer', SimpleImputer(strategy='median')),
    ('attribs_adder', CombinedAttributesAdder()),
    ('std_scaler', StandardScaler())
])
```

In [87]:
```
housing_num_tr = num_pipeline.fit_transform(housing_num)
housing_num_tr.shape
```

Out[87]:
```
(16512, 11)
```

So far, we have handeled categorical/continuous columns separately. It would be better if we had a single transformer that is able to transform all columns.

`ColumnTransformer` s to the rescue:

In [88]:
```
from sklearn.compose import ColumnTransformer
```

In [89]:
```
num_attribs = housing_num.columns.tolist()
cat_attribs = ["ocean_proximity"]
```

In [90]:
```
full_pipeline = ColumnTransformer([
    ("num", num_pipeline, num_attribs),
    ("cat", OneHotEncoder(), cat_attribs)
])
```

In [91]:
```
housing_prepared = full_pipeline.fit_transform(housing)
housing_prepared.shape
```

5. Select & Train a Model

Training & Evaluating on the Training Set

Train a Linear Regression model:

In [92]:
```
from sklearn.linear_model import LinearRegression
```

In [93]:
```
lin_reg = LinearRegression()
```

In [94]:
```
lin_reg.fit(X=housing_prepared, y=housing_labels)
```

Out[94]:
```
LinearRegression()
```

In a Jupyter environment, please rerun this cell to show the HTML representation or trust the notebook.
On GitHub, the HTML representation is unable to render, please try loading this page with nbviewer.org.

Let's try the model on a few instances from the training set:

In [95]:
```
some_data = housing.iloc[:5]
```

In [96]:
```
some_labels = housing_labels.iloc[:5]
```

In [97]:
```
some_data_prepared = full_pipeline.transform(some_data)
```

In [98]:
```
print("Predictions: ", lin_reg.predict(some_data_prepared))
```

```
Predictions:  [ 85657.90192014 305492.60737488 152056.46122456 186095.70946094
 244550.67966089]
```

In [99]:
```
print("Labels: ", some_labels.tolist())
```

```
Labels:  [72100.0, 279600.0, 82700.0, 112500.0, 238300.0]
```

It works, although the predictions are not exactly accurate.

Let's measure the performance of our model using the RMSE metric.

In [100…
```
from sklearn.metrics import mean_squared_error
```

In [101…
```
housing_predictions = lin_reg.predict(housing_prepared)
```

In [102…
```
lin_mse = mean_squared_error(housing_labels, housing_predictions)
```

In [103…
```
lin_rmse = np.sqrt(lin_mse)
lin_rmse
```

Out[103…
```
68627.87390018745
```

Most districts median housing values range between 120K to 265K, so an average error of 68K is not good.

This is an example of a model overfitting the data. When this happens, it can mean two things:

- The features do not provide enough information to make better predictions.
- The model is not powerful enough, meaning its hypothesis space is narrow.

The main ways to tackle underfitting:

- To feed the model better features.
- To select a more powerful model.
- To loosen the model's restrictions.

This model is not regularized, which rules out the last option. We could try to input more features, but let's start by testing a more powerful model.

Let's try out `DecisionTreeRegressor`, this is a powerful model, capable of finding non-linear relationships within the data:

In [104…
```
from sklearn.tree import DecisionTreeRegressor
```

In [105…
```
tree_reg = DecisionTreeRegressor()
```

In [106…
```
tree_reg.fit(X=housing_prepared, y=housing_labels)
```

Out[106…
```
DecisionTreeRegressor()
```

In a Jupyter environment, please rerun this cell to show the HTML representation or trust the notebook.
On GitHub, the HTML representation is unable to render, please try loading this page with nbviewer.org.

In [107…
```
housing_predictions = tree_reg.predict(housing_prepared)
```

In [108…
```
tree_mse = mean_squared_error(y_true=housing_labels, y_pred=housing_predictions)
```

In [109…
```
tree_rmse = np.sqrt(tree_mse)
tree_rmse
```

Out[109…
```
0.0
```

Better Evaluation using Cross-Validation

One way to evaluate our model is to use `train_test_split()` again on the training set, extract a validation set and evaluate our iterative models on it.

A great alternative is to use K-fold cross-validation. We randomly split the training data into 10 folds, we iteratively train the model on 9 folds and evaluate on 1, doing this 10 times.

We will endup with `10` metric scores:

In [110…
```
from sklearn.model_selection import cross_val_score
```

In [111…
```
scores = cross_val_score(estimator=tree_reg, X=housing_prepared,
                         y=housing_labels, scoring='neg_mean_squared_error', cv=10)
```

In [112…
```
tree_rmse_scores = np.sqrt(-scores)
```

`scikit-learn`'s cross validation features expect a utility function (the greater the better) rather than a cost function (the lower the better). That's why we used `ned_mean_squared_error` and we negated it at RMSE evaluation.

In [113…
```
def display_scores(scores):
    print("Scores:", scores)
    print("Mean:", scores.mean())
    print("Standard Deviation:", scores.std())
```

In [114…
```
display_scores(tree_rmse_scores)
```

```
Scores: [73420.18119578 69564.42303171 68891.37403651 71450.13832167
 69371.93163844 77144.32132592 70645.53949428 73310.3218479
 68484.47299548 70726.35627711]
Mean: 71300.90601648012
Standard Deviation: 2528.456433119772
```

The decision tree seems to perform worse than the linear regression model!

We should notice that cross validation allows us to not only get an estimate of the performance of your model (mean), but how precise it is (std). We would not have this estimation if we used only one validation set. However, cross-validation comes at the cost of training the model several times, which is not always possible.

Let's compute the same scores for the linear regression model just to be sure:

In [115…
```
scores = cross_val_score(estimator=lin_reg, X=housing_prepared,
                         y=housing_labels, scoring='neg_mean_squared_error', cv=10)
```

In [116…
```
lin_rmse_scores = np.sqrt(-scores)
```

In [117…
```
display_scores(lin_rmse_scores)
```

```
Scores: [71762.76364394 64114.99166359 67771.17124356 68635.19072082
 66846.14089488 72528.03725385 73997.08050233 68802.33629334
 66443.28836884 70139.79923956]
Mean: 69104.07998247063
Standard Deviation: 2880.3282098180634
```

That's right! the decision tree model is overfitting so badly that it performs worse than the linear regression model.

Let's try one last model now, the random forest regressor. Random forests work by training many decision trees on random feature subsets then average out their predictions.

Building a model on top of many other models is called **Ensemble Learning**.

In [118…
```
from sklearn.ensemble import RandomForestRegressor
```

In [119…
```
forest_reg = RandomForestRegressor()
```

In [120…
```
forest_reg.fit(X=housing_prepared, y=housing_labels)
```

Out[120…
```
RandomForestRegressor()
```

In a Jupyter environment, please rerun this cell to show the HTML representation or trust the notebook.
On GitHub, the HTML representation is unable to render, please try loading this page with nbviewer.org.

In [121…
```
forest_mse = mean_squared_error(y_true=housing_labels, y_pred=forest_reg.predict(X=housing_prepared))
```

In [122…
```
forest_rmse = np.sqrt(forest_mse)
forest_rmse
```

Out[122…
```
18677.177813034952
```

In [ ]:
```
scores = cross_val_score(estimator=forest_reg, X=housing_prepared,
                         y=housing_labels, scoring='neg_mean_squared_error', cv=10)
```

In [ ]:
```
forest_rmse_scores = np.sqrt(-scores)
```

In [ ]:
```
display_scores(scores=forest_rmse_scores)
```

This is much better, random forests seem very promissing. We should notice, however, that the RMSE on the training set is still much lower then the validation RMSE, meaning the model overfitted, but not as badly as the decision tree model. Possible solutions to overfitting are:

- Getting more training data
- Simplifying the model
- Regularizing the model

We should save any model after training so that we can come back to it at any time you want. We make sure to save both the hyper-parameters and the parameters (weights) of the model. We can easily save scikit-learn models using Python's `joblib`:

In [ ]:
```
import joblib
```

In [ ]:
```
joblib.dump(value=forest_reg, filename='models/01/forest_reg.m')
```

In [ ]:
```
# & Later
forest_reg = joblib.load(filename='models/01/forest_reg.m')
```

6. Fine-Tune Your Model

Grid Search

In [ ]:
```
from sklearn.model_selection import GridSearchCV
```

In [ ]:
```
param_grid = [
    {'n_estimators': [3, 10, 30], 'max_features': [2, 4, 6, 8]},
    {'bootstrap': [False], 'n_estimators': [3, 10], 'max_features': [2, 3, 4]}
]
```

In [ ]:
```
forest_reg = RandomForestRegressor()
```

In [ ]:
```
grid_search = GridSearchCV(estimator=forest_reg, param_grid=param_grid, scoring='neg_mean_squared_error', cv=5, return_trai
```

In [ ]:
```
grid_search.fit(X=housing_prepared, y=housing_labels)
```

If we can't guess an initial quality search grids, we can start with powers of 10 then zoom in once we have the best estimate.

The model will first explore 3×4 combinations of hyper-parameters, then jump to the 2nd hyper-parameter space and try $1 \times 2 \times 3$. For each combination, it will train 5 times using the cross validation strategy, all in all: It will train **90** different model variations.

In [ ]:
```
grid_search.best_params_
```

We can also get the best estimator directly:

In [ ]:
```
grid_search.best_estimator_
```

When `GridSearchCV` finds the best estimator, it will retrain it on the whole training set. This can be controlled by the parameter `refit=True` (by default)

In [ ]:
```
cvres = grid_search.cv_results_
```

In [ ]:
```
for mean_score, params in zip(cvres['mean_test_score'], cvres['params']):
    print(np.sqrt(-mean_score), params)
```

In this example, the best hyper-parameter combination is: `50110.7370892457 {'max_features': 6, 'n_estimators': 30}` with an average RMSE of 50110. The model performs slightly better than a random forest with default hyper-parameters.

Randomized Search

The grid search is fine when you're exploring a few hyper-parameter combinations, but when the search space is big though, it is better to use `RandomizedSearchCV` instead. It works almost in the same way of a grid search, but it try out a limited randomly selected number of hyper-paraemeters for each iteration. This approach has two main benefits:

- If we let this approach run for 1,000 iterations, it will explore 1,000 values for each hyper-parameters, instead of combining each unique value.
- By setting the number of iterations, we can control computing resources much more effectively than doing Grid search.

Ensemble Methods

Another way to fine-tune your model is to combine the models that work best. Usually, the ensemble model will perform better than any part of the model, especially if its models are producing different errors.

Analyze the best models & their errors

In [ ]:
```
feature_importances = grid_search.best_estimator_.feature_importances_
(feature_importances*100).astype(int)
```

In [ ]:
```
extra_attribs = ["rooms_per_hhold", "pop_per_hhold", "bedrooms_per_room"]
```

In [ ]:
```
cat_encoder = full_pipeline.named_transformers_['cat']
```

In [ ]:
```
cat_one_hot_attributes = cat_encoder.categories_[0].tolist()
```

In [ ]:
```
attributes = num_attribs + extra_attribs + cat_one_hot_attributes
```

In [ ]:
```
# sorted(zip(feature_importances, attributes), reverse=True)
dict(zip(feature_importances, attributes))
```

With this information, we might want to start dropping some of the attributes to simplify the model (ex. only one `ocean_proximity` value is important).

Evaluate your system on the test set

After tweaking the system for a while, we finally have a model that can be evaluated on the test set. There is nothing special about this process, we reproduce the same steps you used with training data to benchmark the model.

However, we should call `transform()`, and not `fit_transform()`.

In [ ]:
```
final_model = grid_search.best_estimator_
```

In [ ]:
```
X_test = strat_test_set.drop(labels='median_house_value', axis=1)
y_test = strat_test_set['median_house_value'].copy()
```

In [ ]:
```
X_test_prepared = full_pipeline.transform(X=X_test)
```

In [ ]:
```
final_predictions = final_model.predict(X=X_test_prepared)
```

In [ ]:
```
final_mse = mean_squared_error(y_true=y_test, y_pred=final_predictions)
```

In [ ]:
```
final_rmse = np.sqrt(final_mse)
final_rmse
```

In some cases, such a point estimate of the generalization error won't be enough for us to launch it in production. We might want to create a confidence interval of 95% around the metric.

In some cases, such a point estimate of the generalization error won't be enough for us to launch it in production. We might want to create a confidence interval of 95% around the metric.

For this, we use the individual predictions for each test set element.

In [ ]:
```
from scipy import stats
```

In [ ]:
```
confidence = .95
```

In [ ]:
```
squared_errors = (y_test - final_predictions) ** 2
```

In [ ]:
```
np.sqrt(stats.t.interval(confidence, len(squared_errors) - 1, loc=squared_errors.mean(), scale=stats.sem(squared_errors)))
```

If we do a lot of hyper-parameter fine-tuning, we will endup with a slightly worse performance on the test set because we will sometimes overfit to the changing validation set. This didn't happen now, but when it happens, resist the temptation to go back and do more fine-tuning to have better results for the test set.

In our case with the California dataset, our system didn't actually beat the experts system (with 20% error). But management still decided to launch the service to free some time for its experts to work on other tasks.

7. Launch, Monitor, & Maintain your system

2.3 Experiment - 3

2.3.1 Question:

Use an appropriate data set for building the decision tree (ID3) and apply this knowledge to classify a new sample.

2.3.2 Code with Output:

In [1]:
```
import numpy as np
import pandas as pd
eps = np.finfo(float).eps
from numpy import log2 as log
```

In [22]:
```
df=pd.read_csv('/content/play_tennis.csv')
df = df.drop('day',axis=1)
```

In [23]:
```
df.head(14)
```

Out[23]:

	outlook	temp	humidity	wind	play
0	Sunny	Hot	High	Weak	No
1	Sunny	Hot	High	Strong	No
2	Overcast	Hot	High	Weak	Yes
3	Rain	Mild	High	Weak	Yes
4	Rain	Cool	Normal	Weak	Yes
5	Rain	Cool	Normal	Strong	No
6	Overcast	Cool	Normal	Strong	Yes
7	Sunny	Mild	High	Weak	No
8	Sunny	Cool	Normal	Weak	Yes
9	Rain	Mild	Normal	Weak	Yes
10	Sunny	Mild	Normal	Strong	Yes
11	Overcast	Mild	High	Strong	Yes
12	Overcast	Hot	Normal	Weak	Yes
13	Rain	Mild	High	Strong	No

In [24]:
```
print(f'Rows: {df.shape[0]}, Columns: {df.shape[1]}')
```

```
Rows: 14, Columns: 5
```

In [25]:

2.8 Experiment - 8

2.8.1 Question:

a) Implement Random forest ensemble method on a given dataset.
b) Implement Boosting ensemble method on a given dataset.

2.8.2 Code with Output:

a) Random Forest:

```
import pandas as pd
import numpy as np
import matplotlib.pyplot as plt
import seaborn as sns

%matplotlib inline
sns.set_style("whitegrid")
plt.style.use("fivethirtyeight")
```

```
df = pd.read_csv("/content/diabetes.csv")
df.head()
```
